CSE 12 — Basic Data Structures

[Slides borrowed/adapted from slides by Marina Langlois and Christine Alvarado]

Analyzing the worst case

```
boolean find( String[] theList, String toFind ) {
  for ( int i = 0; i < theList.length; i++ ) {
    if ( theList[i].equals(toFind) )
      return true;
  }
  return false;
}
boolean fastFind( String[] theList, String toFind ) {
  return false;
}</pre>
```

Which method is faster?

- A. find
- B. fastFind
- C. They are about the same

Running time: What version of the problem are you analyzing

- One part of figuring out how long a program takes to run is figuring out how "lucky" you got in your input.
 - You might get lucky (best case), and require the least amount of time possible
 - You might get unlucky (worst case) and require the most amount of time possible
 - Or you might want to know "on average" (average case) if you are neither lucky or unlucky, how long does an algorithm take.

Almost always, what we care about is the WORST CASE or the AVERAGE CASE.

Best case is usually not that interesting, unless we can prove it's slow!

In CSE 12 when we do analysis, we are doing **WORST CASE** analysis unless otherwise specified.

Big-O
$$g(N) = N$$
 $\Rightarrow f_{i,s,i+1}(N) = 1 + N + 2(N-1) + 1$
 $\Rightarrow f_{i,s,i+1}(N) = 3 + 3N + 3(N(N-1))$
 $\Rightarrow f_{i,s,i+1}(N) = 4 + 3N$

We say a function f(n) is "big-O" of another function g(n), and write f(n) = O(g(n)), if there are positive constants c and n_0 such that:

• $f(n) \le c g(n)$ for all $n \ge n_0$.

In other words, for large n, can you multiply g(n) by a constant and have it always be bigger than or equal to f(n)

Steps for calculating the Big O (Theta, Omega) bound on code or algorithms

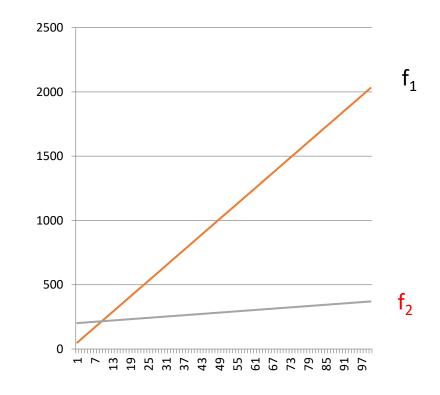

- 1. Identify the assumptions you're making about input and the case you're studying best, worst, average?
- 2. Count the number of instructions in your code (or algorithm) as precisely as possible as a function the size of your input (e.g. the length of the array). Call this f(n)
- 3. Summarize your findings by relating f(n) to a simpler g(n) such that f(n) = O(g(n))

$$f_2 is * O(f_1)$$

A. TRUE

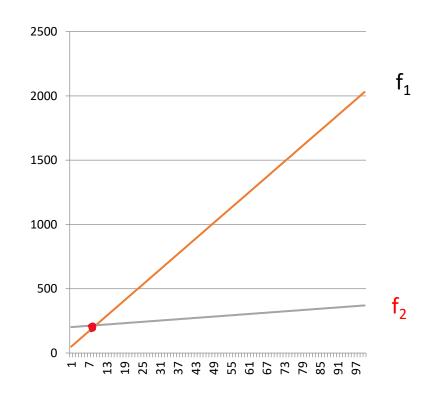

B. FALSE

Why or why not?

^{*} You can't actually tell if you don't know the function, because it could do something crazy just off the graph, but we'll assume it doesn't.

- f_2 is $O(f_1)$ because $f_1 > f_2$ (after about n=10, so we set $n_0 = 10$)
 - f₁ is clearly an upper bound on f₂ and that's what big-O is all about

f_1 is $O(f_2)$

f(n) = O(g(n)), if there are positive constants c and n_0 such that $f(n) \le g(n)$ for all $n \ge n_0$.

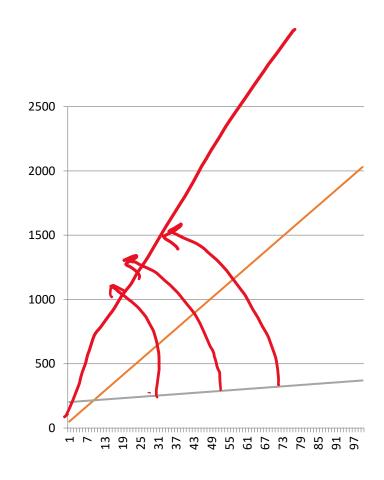

fa

- A. TRUE
- B. FALSE

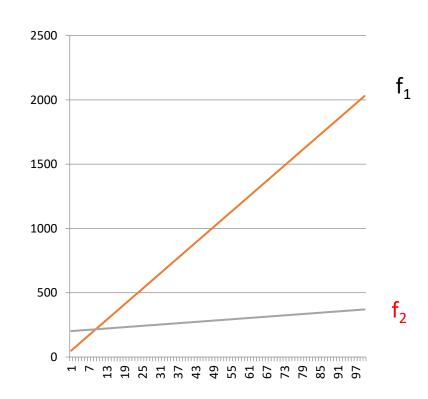

Why or why not?

In other words, for large n, can you multiply f_2 by a constant and have it always be bigger than f_1 for large enough n?

$$C = 1000$$

- f_2 is $O(f_1)$ because $f_1 > f_2$ (after about n=10, so we set $n_0 = 10$)
 - f₁ is clearly an upper bound on f₂ and that's what big-O is all about
- But $f_1 = O(f_2)$ as well!
 - We just have to use the
 "c" to adjust so f₂ that it
 moves above f₁

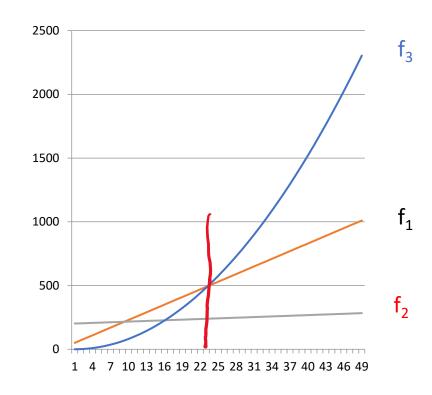

$$f_1$$
 is $O(f_3)$

B. FALSE

Why or why not?

 f_3 is $O(f_1)$

A. TRUE

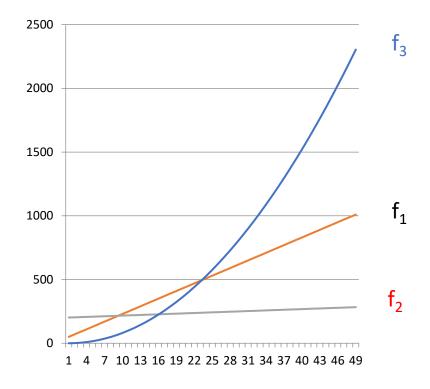

B) FALSE

Why or why not?

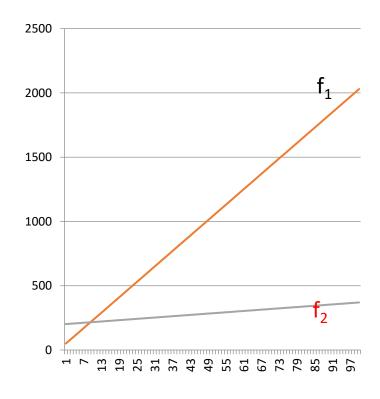

$$f_1 = O(f_3) but f_3 \neq O(f_1)$$

There is no way to pick a c that would make an O(n) function (f₁) stay above an O(n²) function (f₃).

Common Big-O confusions when trying to argue that f_2 is $O(f_1)$:

- What if we multiply f₂ by a large constant, so that c*f₂ is larger than f₁? Doesn't that mean that f₂ is not O(f₁)?
 No, because the definition asks us to find some constants that fit. Having some other constants that don't work is fine.
- What about when n is less than 10? Isn't f2 larger than f1?
 Remember, we get to pick our n0, and only consider n larger than n0.

Shortcuts for calculating

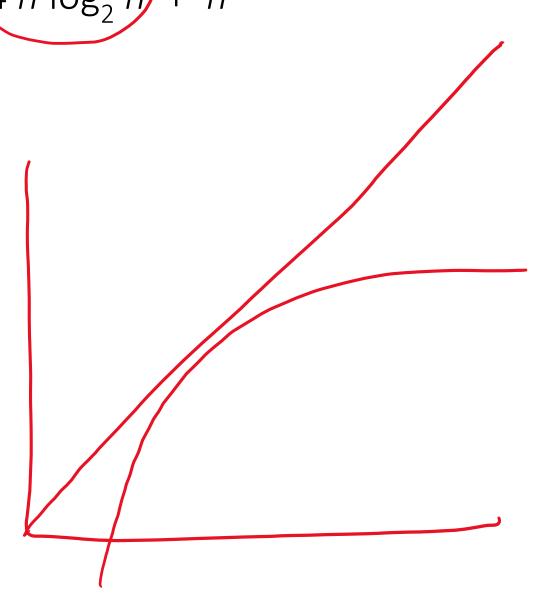

Big-O analysis starting with a function characterizing the growth in cost of the algorithm

Let
$$f(n) = 3 \log_2 n + 4 n \log_2 n + n$$

Which of the following is true?

A.
$$f(n)$$
 is $O(log_2 n) \times$

- B. f(n) is O(nlog₂n)
- C. f(n) is $O(n^2)$ $N \not *_N$
 - D. f(n) is $O(n) \times$
- (E) More than one of these

Let
$$f(n) = 546 + 34n + 2n^2$$

$$2\nu^2 + 2\nu^2 + 2\nu^2$$

Which of the following is NOT a correct bound?

A.
$$f(n)$$
 is $O(2^n)$

B.
$$f(n)$$
 is $O(n^2)$

D.
$$f(n)$$
 is $O(n^3)$

Let
$$f(n) = 2^n + 14n^2 + 4n^3$$

Which of the following is true?

- A f(n) is $O(2^n)$
- B. f(n) is $O(n^2)$
- C. f(n) is O(n)
- D. f(n) is $O(n^3)$
- E. More than one of these

Let
$$f(n) = 100$$

Which of the following is NOT a correct bound?

- A. f(n) is $O(2^n)$
- B. f(n) is $O(n^2)$
- C. f(n) is O(n)
- D. f(n) is $O(n^{100})$
- E. None of these

O is an upper bound Ω is a *lower bound*

We say a function f(n) is "big-omega" of another function g(n), and write $f(n) = \Omega(g(n))$, if there are positive constants c and n_0 such that:

• $f(n) \ge c g(n)$ for all $n \ge n_0$.

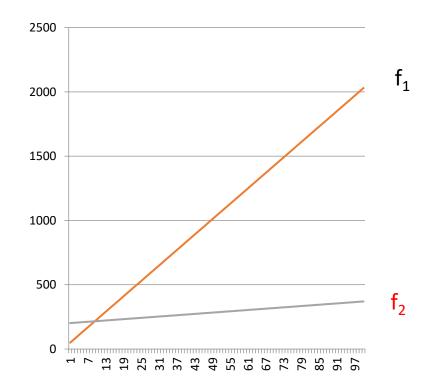

In other words, for large n, can you multiply g(n) by a constant and have it always be smaller than or equal to f(n)

f_2 is $\Omega(f_1)$

- A. TRUE
- B. FALSE

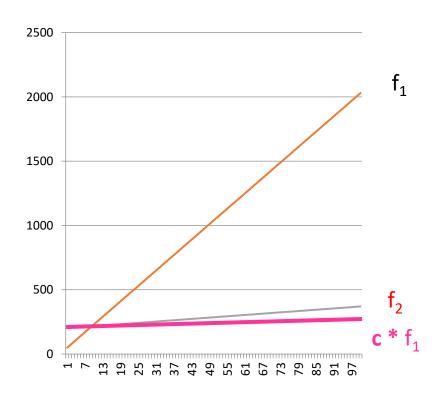

Why or why not?

In other words, for large n, can you multiply f_1 by a positive constant and have it always be smaller than f_2

 $f(n) = \Omega(g(n))$, if there are positive constants c and n_0 such that $f(n) \ge c * g(n)$ for all $n \ge n_0$.

- f_1 is $\Omega(f_2)$ because $f_1 > f_2$ (after about n=10, so we set $n_0 = 10$)
 - f_2 is clearly a *lower bound* on f_1 and that's what big- Ω is all about
- But f_2 is $\Omega(f_1)$ as well!
 - We just have to use the "c" to adjust so f₁ that it moves below f₂

 $f(n) = \Omega(g(n))$, if there are positive constants c and n_0 such that $f(n) \ge c * g(n)$ for all $n \ge n_0$.

$$f_3$$
 is $\Omega(f_1)$

A. TRUE

B. FALSE

Why or why not?

 $f(n) = \Omega(g(n))$, if there are positive constants c and n_0 such that $f(n) \ge c * g(n)$ for all $n \ge n_0$.

$$f_1$$
 is $\Omega(f_3)$

A. TRUE

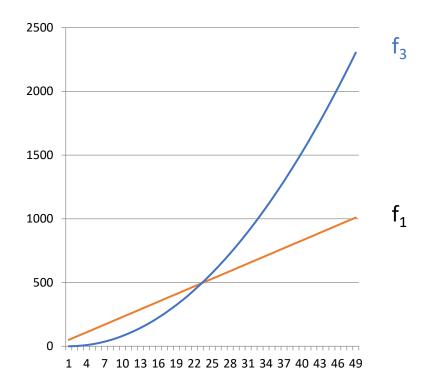

B. FALSE

Why or why not?

$$f_3 = \Omega(f_1) but f_1 \neq \Omega(f_3)$$

 There is no way to pick a c that would make an O(n²) function (f₃) stay below an O(n) function (f₁).

Summary

Big-O

- Upper bound on a function
- f(n) = O(g(n)) means that we can expect f(n) will always be under the bound g(n)
 - But we don't count n up to some starting point n₀
 - And we can "cheat" a little bit by moving g(n) up by multiplying by some constant c

Big-Ω

- Lower bound on a function
- f(n) = Ω(g(n)) means that we can expect f(n) will always be over the bound g(n)
 - But we don't count n up to some starting point n₀
 - And we can "cheat" a little bit by moving g(n) down by multiplying by some constant c

Big-θ

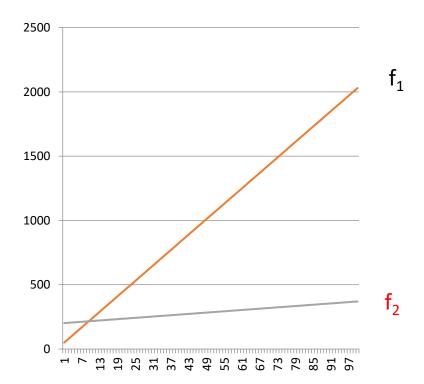

- Tight bound on a function.
- If f(n) = O(g(n)) and $f(n) = \Omega(g(n))$, then $f(n) = \theta(g(n))$.
- Basically it means that f(n) and g(n) are interchangeable
- Examples:
 - $3n+20 = \theta(10n+7)$
 - $5n^2 + 50n + 3 = \theta(5n^2 + 100)$

 f_1 is $\Theta(f_2)$

A. TRUE

B. FALSE

Why or why not?

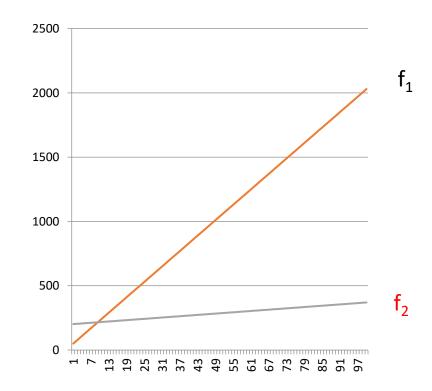

f_1 is $\Theta(f_2)$

A. TRUE

B. FALSE

Why or why not?

Since f_1 is $O(f_2)$ and $\Omega(f_2)$, it is also $O(f_2)$ (this is the definition of big-Theta)

 f_1 is $\Theta(f_3)$

A. TRUE

B. FALSE

Why or why not?

Big-θ and sloppy usage

- Sometimes people say, "This algorithm is $O(n^2)$ " when it would be more precise to say that it is $\theta(n^2)$
 - They are intending to give a tight bound, but use the looser "big-O" term instead of the "big- θ " term that actually means tight bound
 - Not wrong, but not as precise
- I don't know why, this is just a cultural thing you will encounter among computer scientists

Count how many times each line executes, then say which $\Theta()$ statement(s) is(are) true.

A.
$$f(n) = \theta(2^n)$$

B.
$$f(n) = \theta(n^2)$$

C.
$$f(n) = \theta(n)$$

D.
$$f(n) = \theta(n^3)$$

Count how many times each line executes, then say which $\Theta()$ statement(s) is(are) true.

```
int sumTheMiddle(int[] arr) {
  int range = 100;
  int start = arr.length/2 - range/2;
  int sum = 0;
  for (int i=start; i<start+range; i++)
  {
    sum += arr[i];
  }
  return max;
}</pre>
```

A.
$$f(n) = \theta(2^n)$$

B.
$$f(n) = \theta(n^2)$$

C.
$$f(n) = \theta(n)$$

D.
$$f(n) = \theta(1)$$

Count how many times each line executes, then say which $\Theta()$ statement(s) is(are) true.

```
int sumTheMiddle(int[] arr) {
  int range = arr.length/100;
  int start = arr.length/2 - range/2;
  int sum = 0;
  for (int i=start; start+range; i++)
  {
    sum += arr[i];
  }
  return sum;
}
```

A.
$$f(n) = \theta(2^n)$$

B.
$$f(n) = \theta(n^2)$$

C.
$$f(n) = \theta(n)$$

D.
$$f(n) = \theta(1)$$

E. None of these
$$(assume \ n = arr.length)$$

With worst case analysis, which algorithm has the better (smaller) Big-O bound?

```
boolean find( String[] theList, String toFind ) {
  for ( int i = 0; i < theList.length; i++ ) {
    if ( theList[i].equals(toFind) )
      return true;
  }
  return false;
}
boolean fastFind( String[] theList, String toFind ) {
  return false;
}</pre>
```

- A. find
- B. fastFind
- C. They are the same

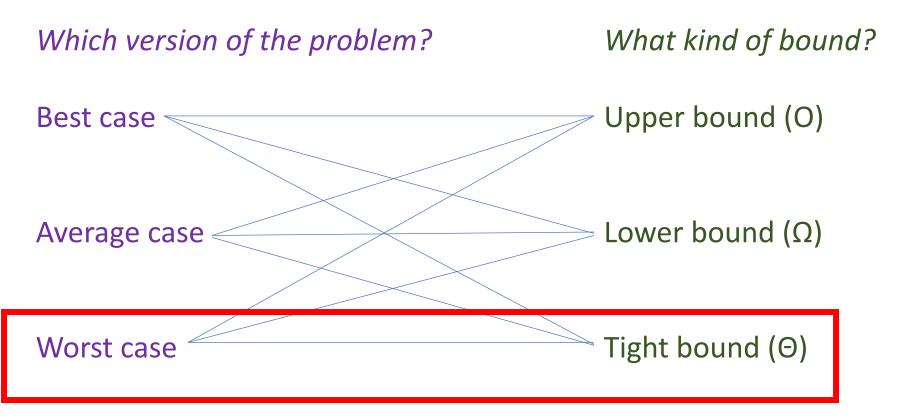

With best case analysis, which algorithm has the better Big-O bound?

```
boolean find( String[] theList, String toFind ) {
  for ( int i = 0; i < theList.length; i++ ) {
    if ( theList[i].equals(toFind) )
      return true;
  }
  return false;
}
boolean fastFind( String[] theList, String toFind ) {
  return false;
}</pre>
```

- A. find
- B. fastFind
- C. They are the same

Big-O means upper bound NOT worst case

The many ways to do running time analysis Any combination of purple and green OK!

Most common combination
